The first one is Is there anyone familiar with a virus going around that will wipe the CMOS on the MB and not allow the machine to post. I have an aunt and a grandmother that have two TOTALLY different boxes that I built them and the only that they have in common is that they send emails back and forth all day. One finally fessed up that her NAV told her that she had a virus that needed to be cleaned. After she rebooted the machine it would not post. I cleared the CMOS on her MSI board and it booted right back up and is working

fine now. The other has a GigaByte GA7ZXE. She will not fess up to having a virus at all, but the symptoms are identical.http://veneziaps.com/updata/ndata/20200902081620.xml

Upon booting the machine will light up and the HD will spin up, but nothing is posing. I cannot for the life of me find in the tree killer manual or the pdf flavor of the manual how to clear the CMOS and start all over. Here is the board link Gigabyte site. If anyone has any suggestion besides disconnecting the battery please let me know. Thanks in advance Thanks for the response. I never found a jumper though. All rights reserved. I am selling this because I have finished my Studies in UK and going back to my home country this summer. Please have a look to my other items that currently selling in Ebay. THX. Get the best experience on your GigabyteTechnology GA7ZXE Motherboard with improved performance, make it easy to create a home network and share all of your favorite items.The GA7ZXE is designed for users who require maximum performance in a mainstream Motherboard. Even with its form factor design, the GA7ZXE doesnt skimp on performance offering the ideal blend of power and efficiency. The GA7ZXE is sure to leave a lasting impression with its easy to use and slim design. Located on the side of the unit, the modular bays innovative latch is designed for easy insertion and removal of the various module options. The GA7ZXE Motherboard only supports AMD Athlon, Duron. The GA7ZXE features two onboard data caches for transferring information to and from the processor. These caches are known as the L1 and L2 caches. The GA7ZXE L1 cache is 64 kilobytes in size, while its L2 cache is rated at either one or two megabytes. When you have a clear idea of which Motherboard best suits your needs, check for its specifications.

As the GA7ZXE is supported by GigabyteTechnology, check if the Motherboard has full support and warranties by its manufacturer, like GA7ZXE specs you will have lots of options from the Motherboard manufacturer to choose from, like the Motherboard processor, Motherboard RAM, its graphics capacity, Motherboard display options and specs, and other features that the Motherboard provides. You should have an idea on what specs you want from your Motherboard and what specs you do not want on your Motherboard, deciding on Motherboard specs may be difficult task to do but like the GA7ZXE specs have, its essential to selecting a Motherboard you need at a price tag that it deserves and that you can afford. Here is a sample GA7ZXE Motherboard specification if you want an initial guide to buy a Motherboard. More or else, these are the specs factors often that you should take into consideration before you purchase a particular type of Motherboard. So, if you are going to use the back panel, you should short the pins mentioned earlier. You cannot use the back panel and the front panel at the same time. If you want to use your headphones using the back panel, short the mentioned pins and connect your headphones to the green header of your back panel audio. If you want to use the front panel, take off the jumper caps and connect the front panel cable. Remember, if you connect the front panel audio cable, you wont be able to use the back panel. If you are going to use the back panel, dont forget to return the jumper caps. Usually the 56 and 910 pins. Hope this helps. Your current case is set up for AC97. You will have to contact Mfg.This is part of Realtecs software. Hope this helps. If you make the call it will be a fix. Good luck. Did you have the power connected still when you took them out and put them back in. If you had power still plugged in you have probably fried the ports. Login to post Heres your geeksteer.

From the manufacturer, heres the manual download link, and anything else youd need supporting this board. Good luck onebadasscoo, and please post back. Just follow these steps and im sure you will have the manual too. It is all there. Best of luck.Sometimes, the floppy disk player runs, at any time. If you could help me, you should be thanked a lot. From lisearia.The BIOS is 7ZXE.FB downloaded from Gigabyte.com for American Megatrend on Windows XP SP3 Answer questions,

We are working every day to make sure our community is one of the best. In fact, this technology is not new as we have seen similar ones but supporting only AMD or INTEL but with different socket types. This is made possible as the South Bridge is common between the K8 and P4 architecture. Both uses the SiS 965 South Bridge. The base board supports Intel P4 LGA775 socket and includes 4 slots of DDR2 667 memory, a 1066FSB, SATA2, GigaLAN, 1394a Firewire, and makes use of the SiS656 Northbridge and a SiS965 Southbridge. The SiS965 Southbridge is shared with the converter card, which is based around the AMD socket 939, and has its own dedicated SiS756 Northbridge, 2 slots of DDR400, power management circuits and a FSB2000T, which are required to run AMD K8 technology. PF88 motherboard supports the latest dual core technology from Intel and AMD. Furthermore, the P4 LGA 775 socket also supports EM64T from Intel. The new PF88 converter card will retail at a third of the cost of purchasing an additional motherboard and ECS will sell its PF88 and compatible motherboards separately to allow users to covert from an Intel platform to the latest AMD technologies at a later date and cost effectively. Does that imply that the CPU is not as superior so you need to buy a upgrade card to upgrade. Well that remains to be seen.

http://gitegrangesdelie.com/images/boss-ph-3-manual.pdf

The next thing is that this board is based on the SiS 756 and SiS 656 North Bridges. As we have not seen any SiS 756 nor SiS 656 Mainboards so far except the reference boards. We might have to wait a while before we get to see the board. We will keep you updated. Another thing is that those who have bought these hybrid solutions from another company, I suspect they might have something up on their sleeves too. I wanted to use this as a nice NT server to host some files, however it is not going as planned. I took the board and put it in my spare case with a 250 Watt supply. Of course doing the jumpers, checking meticulously on the PDF file to make sure I was right. The only thing that wasnt jumpered was the Green jumpers. I added my ribbons IDE and Floppy right after. All I did was put it in a new case, same brand case but just a newer model with slide sides rather than a pulloff top. I then put in the video card and got picture. Long story short, the SmartModem was burnt out somehow because when I put it in it wouldnt POST. I do need to update the bios because on shutdown it is doing that stupid reboot thing. Next is having fun with the next computer after this one is done. Yay for me. GA7ZXE gigabyte 7zxe manual rev. View and Download Gigabyte GA7ZXE user manual online. Gigabyte comes with a a nifty little program called Easytune. Basically it allows you to raise the frontside bus in 1 mhz increments. Good thing too, as there is no way of changing your FSB from the bios, let alone the voltage because of its auto detect feature.Started up sandra, and started the burnin wizard for 30 minutes. That lasted about 12 minutes, the computer crashed. Next i tried 140mhz, 1820 minutes, crashed. Finally i tried 138mhz.Of course this is with the stock AMD heat sink and fan.More over clockability could possibly be achieved, if you used a copper heatsink and additional cooling.Though it not bad for a newbie to get their feet wet, with this budget board. It may not display this or other websites correctly. You should upgrade or use an alternative browser. My PC has a gigabyte mobo model GA7ZXE Rev 2.1 Prior to this I have had no problems from this PC. About a month ago I updated the Bios due to some problems I was having and it took the update but caused my PC to boot up really slow then it began crashing frequently. So today I flashed the bios back to the earlier version. After the reboot the post gets to checking NVRAM. and stops. It never searches for drives nor counts the memory or anything, I have tried everything under the sun. I have used another PC to creat the bootble flash diskette, but the bos never gets to the point of loading the drives. I have removed the CMOS battery for over 10 mins both with the power supply plugged in to the mobo and disconnected from it.

The only jumpers I see are for the CPU clock speed. There is a set of jumpers below it labeled IR. But nowhere in the manual does it explain what IR is, or what it does. If I could get there I could reload a different Bios. The Bios is AMIBIOS the chip has 686 on it. I have looked all over AMIs website adn Gigabytes website. No Luck. I you need to look at the manual for the mobo it can be found at www.gigabyte.com.tw The thing is this is how the Bios looked when I first took it out of the box, but then it would at least see the cdrom so that I could load the sofware from the CDrom. Also I have removed all the peripherals and reseated them. The only thing that I have not removed is the CPU itself. I left the battery out and the power unplugged for over 6 hours. Still no help. Is it possible that the BIOS flash screwed up all 3 memory sticks. Shouldnt there be another set of jumpers to reset the bios. BIOS WIPE maybe Help!!!!!!! PLEASE. Title edited Didou Because if thats the problem, youll either have to use a solder iron, or buy a new motherboard. Im sorry. Not meaning to be rude, but dont have time to go into more details right now One type of NVRAM is SRAM that is made nonvolatile by connecting it to a constant power source such as a battery. Another type of NVRAM uses EEPROM chips to save its contents when power is turned off. In this case, NVRAM is composed of a combination of SRAM and EEPROM chips. A bad flas will cause this problem. IF you took out the battery it should of reset your BIOS to defult. YOu might ahve to get a hold of GIGABYTE and get a new COMS Chip. To reset manual you have to turn off power remove the jumper place it on the two pins it is not on now. Imprinted on the side of the board between where the power switches plug in and the IDE slots are instructions for clearing the CMOS and disabling the bios write protect. But AGAIN there are no jumpers. It does not tell me what jumpers it is refering to.

The only jumpers I see are The one for the CPU clock frequency and some labeled IR. I dont know what IR is. The op manual refers to IR but does not explain what it does. I am beginning to think that Gigabyte left a few things off of this board. The specs on the website says that the board is supposed to have 3 fan connections, so does the manual but there are only 2 fan connections. There is a spot where fan3 should be and it is labeled but the connector is not there. I wonder if they left the jumpers off. I have left the battery unplugged and switched the CPU clock jumpers over and over. NO LUCK. I finally took the battery out and unplugged the power supply from the motherboard. I planned to leave it this way all day and see what happens. I currently have a 350 watt powers supply, should I try a different power supply and a different baattery Unplug the PC and take the battery out. Use a properly bent paperclip, and connect points 2 and 3 to Clear CMOS. Make sure not to connect anything else! Still looking. Friggin Gigabytes webstite isnt very helpful.One of the combinations will do the trick.I tried the combinations with all three of those, no luck.Tonight when I get home I will try to take a digital picture that shows this section of the board and post it so that you can get a visual.Thought Ill just bump up this thread and hopefully some kind person will help me sort it out. Was my old board KT6 Delta MS 6590 Ver 2 and wanted to use it again after not using it for a while. The cpu fan runs and the keyboard lights goes on a while. After that, I get a no display sign on my monitor and no beeps. Was wondering if you guys think that it can still work. Do i need to try to do something to the bios. Tried to take out the battery and used the cmos clear jumper already but nothing happens. Put in my old 1300 thunderbird in in case but it did not work also. I do not have the LED bracket to diagnose the problem on that area.

Have enough parts to build up a second pc for my internet usage so hopefully the board can be saved. Any advice thanks in advance. m2m4m6m Terms of Use Privacy Policy Advertise.
